## Abstract

In our present work the reprocessability of a self-reinforced PP composites (SRPPC) prepared by compression molding was studied. The composite materials (handled separately, based on the related matrix material) were ground, than extruded five times and injection molded after the first and fifth cycle in order to investigate the behavior of the material during reprocessing. As a reference, the matrices of the composites were also reprocessed and injection molded similarly to the composites. On the manufactured specimens static (tensile and flexural) and dynamic mechanical tests (Charpy) were performed. The melting and crystalline characteristics were studied by Differential Scanning Calorimetry (DSC). The probable decomposition caused by multiple extrusions was followed by the Melt Volume Rate (MVR). The results indicated that in the case of commercial materials there is no significant degradation even after multiple reprocessing cycles; therefore the reprocessability of SRPPC products has no hindrance. The presence of  $\alpha$ -iPP reinforcement in the rPP based composites after reprocessing results in increased inclination for crystallization and consequently leads to improved mechanical stiffness compared to rPP neat matrices

Keywords: PP, reprocessing, self-reinforced composite,  $\beta$ -PP

## Introduction

1 The recyclability of polymers and their blends and composites has become very important  
2 issue nowadays. Its importance is represented by the European Union directive on the end-of-  
3 life of vehicles (ELV) [1]. In the automotive industry polypropylene (PP) is one of the most  
4 used polymeric materials. PP has excellent price/performance ratio, it has to be filled and/or  
5 reinforced in order to compete with engineering plastics. Glass fiber (GF) is commonly used  
6 to improve the properties of PP. Nevertheless, the recycling of the PP-GF composites is  
7 difficult. In order to fulfill the aforementioned directives, two possibilities are open: to  
8 improve the recycling technologies in order to be able to recycle more difficult systems or to  
9 develop materials which can be reprocessed easily. For the latter a very promising alternative  
10 is to develop self-reinforced polymer composites (SRPC – the reinforcement and the matrix  
11 belong to the same polymer family but differing in their melting temperatures), because these  
12 composites may be used after reprocessing as a one component material. SRPCs have been  
13 prepared from many polymers, although PP has become widespread in SRPC applications yet.  
14 Any kind of polymer is available for producing SRPCs, which can be processed in fibrous  
15 form.

22  
23  
24  
25  
26  
27  
28  
29 To produce SRPCs suitable processing window (melting temperature difference between  
30 matrix and reinforcement) is necessary. It can be obtained by moulding the polymer fibres  
31 themselves (first only the skin of the fibre melts to become matrix and the core  
32 (reinforcement) remains oriented), called hot compaction, as developed by Ward and Hine [2-  
33 4]. This is a really one-component system, so it can be reprocessed without any difficulties.  
34 The processing window during composite manufacturing can further be increased by selecting  
35 matrix materials having lower melting temperature than the reinforcement (but differing only  
36 slightly in the chemical composition – random PP copolymer (rPP)). This is the basis of the  
37 consolidation of coextruded tapes, developed by the group of Peijs [5-7]. This combination of  
38 two PP materials can also be processed by film-stacking method [8-15]. As a result of  
39 reprocessing of these two-component systems an iPP/rPP blend is obtained, so its  
40 homogeneity and morphology is to be determined [16]. Since PP is a polymorphic polymer, it  
41 has three crystalline modifications: monoclinic ( $\alpha$ ), trigonal ( $\beta$ ), and orthorhombic ( $\gamma$ ) forms  
42 [17-19]. Commercial grades of PP crystallize essentially in the  $\alpha$ -form [20]), however  $\beta$ -iPP  
43 can be prepared easily in the presence of highly active  $\beta$ -nucleating agents [20, 21]. The  
44 melting temperature of  $\beta$ -form is lower than that of the commercial  $\alpha$ -iPP, which provides  
45 possibility to broaden the processing window of self-reinforced PP composite (SRPPC)  
46 products, if  $\alpha$ -iPP is embedded as reinforcement in  $\beta$ -iPP matrix. This kind of composite is

1 really a homocomposite, because of the reinforcement and the matrix differ only in their  
2 crystalline forms [13, 14, 22, 23] (Note that analogous approach was also used for polyamide  
3 (PA6) based self-reinforced composites [24]). Therefore the expected recyclability of these  
4 composites shall be similar to the hot compacted composites.  
5

6  
7 The reprocessability of polypropylenes was studied by several authors. After several injection  
8 molding cycles, the reprocessing may resulted in chain scission, which is mainly caused by  
9 heat loading and mechanical shearing [25]. However, no significant change in the molecular  
10 architecture occurs during several reprocessing cycles of well stabilized commercial PP  
11 grades. With increasing number of cycles or with increasing reprocessing temperature, only a  
12 little reduction can be observed in the average molecular mass [26, 27]. Many studies have  
13 been reported no change or only a slight decrease in the tensile strength and in molecular  
14 mass of the material [28-30]. The impact properties and the elongation at break are improved  
15 however, as a consequence of the decreasing stiffness after reprocessing. Additionally, the  
16 melt viscosity and the elongation at break also decrease [31].  
17

18  
19 After reprocessing of reinforced polypropylenes, the mechanical properties (impact strength,  
20 flexural strength and modulus) were decreasing due to mainly the fiber breakage. These  
21 phenomenons were investigated in the literature [25, 28, 31]. The rheological tests showed the  
22 decrease of the viscosity. This is caused by chain scissions and reinforcing fiber breakage  
23 induced by reprocessing and grinding.  
24

25  
26 Since the reprocessing of PP and its composites has been widely published but there are no  
27 studies for the reprocessing of SRPPCs according to the author's knowledge. Therefore the  
28 goal of this work is to study the reprocessability of the SRPPCs. The composite materials  
29 (handled separately based on the related matrix material) were ground, than extruded five  
30 times and the properties were studied after the first and fifth extrusion, respectively, in order  
31 to investigate the melting characteristics and mechanical properties of the samples during  
32 reprocessing. From the granulated materials different specimens were produced by injection  
33 molding and tested.  
34

## 35 **Materials, their processing and testing**

### 36 **Materials**

37  
38 Composite specimens prepared and tested previously and cutting scraps were used in our  
39 present study [13, 14]. The composite sheets are composed of a plain woven fabric as  
40 reinforcement (presented in our earlier work [14], composed of highly stretched split PP  
41 yarns) and three kinds of PP as matrix material ( $\beta$  form of isotactic PP homopolymer

1 (H388F); random PP copolymer (R351F), and  $\beta$  form of the latter. The non-nucleated PPs  
2 were provided by TVK Co. (Tiszaújváros, Hungary) and exhibited a melt flow index of 8  
3  $\text{g}(10\text{min})^{-1}$  (at 230°C and 2.16 kg of load). 0.15 wt% of calcium salt of suberic acid (Ca-sub)  
4 was introduced into PP as a selective  $\beta$ -nucleating agent in order to prepare  $\beta$ -nucleated  
5 samples [32]. The detailed processing method of all SRPPC specimens was described in our  
6 earlier work [13, 14]. Thin film was extruded as matrix material and a woven fabric  
7 composed of highly stretched PP tapes was applied as reinforcement. Table 1 contains the  
8 melting temperature of the components.  
9

10 Composite sheets with a thickness of 2.5 mm and a nominal reinforcement (i.e.  $\alpha$ -PP fabric)  
11 content of 50 wt% were produced by compression moulding of a film-stacked package at 7  
12 different processing temperatures. They are selected at 5, 10, 15, 20, 25, 30 and 35°C above  
13 the relevant matrix melting temperature. For the latter the Differential Scanning Calorimetry  
14 (DSC) melting peak was considered (cf. Table 1). Due to the different processing  
15 temperatures, the consolidation quality of the resulting composites was also different. The  
16 tested (failed) specimens and cutting scrap were collected separately according to the matrix  
17 material.  
18

### 29 **Grinding and extrusion**

30 The collected tested composite specimens and cutting scrap were ground with Plastics  
31 Machinery Granulatore GRS 152\_302 grinder. The ground composite material was  
32 inhomogeneous; significant amount of reinforcement material from the poorly consolidated  
33 SRPPCs was debonding from the matrix. Therefore the particle size distribution was also  
34 inhomogeneous.  
35

36 The ground material was extruded five times with a Brabender Plasti-Corder PL 2100 twin  
37 screw extruder and then granulated. The extrusion temperature were set to 190°C, 195°C,  
38 200°C, 200°C from the feeder to the die. The screw revolution  $8 \text{ min}^{-1}$  for the ground material  
39 (first cycle) and  $25 \text{ min}^{-1}$  for the granulated material (2-5<sup>th</sup> cycle) and for matrix materials was  
40 set. To compare, the original matrix materials were also extruded five times.  
41

### 50 **Injection molding**

51 From the granulated materials after the first and fifth extrusion different (tensile and Charpy)  
52 specimens were manufactured on an Arburg Allrounder 320C 600-250 injection molding  
53 machine. Table 2 contains the injection molding parameters. The temperature zones were set  
54 to 185°C, 195°C, 200°C, 205°C, 210°C from the feeder to the mold. The injection molded  
55 materials are listed in Table 3. Note that composite materials with random PP copolymer  
56  
57  
58

62  
63  
64  
65

1 matrix (regardless of its crystalline form) became a blend due to the reprocessing at higher  
2 temperature (considerably higher than the melting temperature of the reinforcement).  
3 However, referring to the initial materials, we will further designate it as composite.  
4  
5

### 6 **Specimens and their testing**

7 To obtain the flowability and the degradation, Melt Volume Rate (MVR) test were performed  
8 on the materials after each process cycle on CEAST Modular Melt Flow 7027.000 machine.  
9 The test parameters were the follow: load: 2160 g, holding time: 240 s, temperature: 230°C,  
10 sample mass: 8 g.  
11  
12

13 The crystallization and melting characteristics of the specimens were studied by DSC. The  
14 melting curves were recorded by a Pelkin Elmer DSC 7 apparatus. Samples having a mass of  
15 3-5 mg were scanned at 10°Cmin<sup>-1</sup> heating ( $v_h$ ) and cooling ( $v_c$ ) rates. In order to erase  
16 thermal and mechanical history, the samples were heated up to 220°C and held there for 5  
17 min. Since  $\beta$ -form of PP samples cooled to below 100°C, recrystallize into the  $\alpha$ -form during  
18 the partial melting of the  $\beta$ -phase [33], the end temperature of cooling ( $T_R$ ) was set to 100°C  
19 during non-isothermal crystallization. This setting prevents  $\beta\alpha$ -recrystallization, so the  
20 polymorphic composition of the blends can be determined accurately from the melting curves  
21 [20, 21].  
22  
23

24 Static tensile tests were performed on dumbbell specimens (according to standard ISO  
25 527:1999) using a Zwick Z020 universal testing machine with a crosshead speed of  
26 5 mm min<sup>-1</sup>.  
27  
28

29 Charpy impact tests were performed on Type 1 notched rectangular specimens (according to  
30 standard ISO 179:2001) on a Ceast Resil Impactor Junior P/N 6963.000 using the following  
31 settings: starting angle of the hammer: 150°; maximum energy: 15 J.  
32  
33

34 All mechanical tests were performed at room temperature and at least five specimens were  
35 tested.  
36  
37

## 38 **Results and Discussion**

### 39 **MVR**

40 The MVR of the materials processed once and five times can be seen on Figure 1. One can  
41 observe that MVR does not change significantly with increasing of the processing cycles. The  
42 more or less constant MVR values hint that the stability of the polymer is good and no  
43 thermal degradation occurs during the multiplied processing cycles. In case of ground  
44 SRPPCs tested prior to first extrusion, the flowability has considerably higher scatter than  
45 after extrusion. The reason is that the particle size of the ground material was inhomogeneous.

63  
64  
65

1 The fluidity of the extruded SRPPCs is lower than that of matrices, since the fluidity of the  
2 neat material of the reinforcing tape production (foil extrusion grade) is much lower.  
3

## 4 **Melting and crystallization characteristics**

### 5 **Effect of blending**

6  
7  
8  
9 The rPP-based SRPPC is a “two-component” system, because the copolymer matrix contains  
10 ca. 3-5 wt% ethylene co-monomers distributed randomly. As a result of the melt reprocessing  
11 it is important to know the resulting structure of iPP/rPP blend. The melting curves of  $\alpha$ -PP  
12 (the neat material of  $\alpha$ -PP reinforcement) and  $\alpha$ -rPP matrices and the blend of  $\alpha$ -rPP matrix  
13 and  $\alpha$ -PP tapes ( $\alpha$ -PP composite based sample) are displayed in Figure 2. The calorimetric  
14 traces indicate clearly that one peak appears during the melting and crystallization of  
15 composite materials indicating the miscibility of iPP and rPP in the reprocessed  $\alpha$ -PP  
16 composite based sample. The melting peak at 164 °C relates to  $\alpha$ -PP and,  $\alpha$ -rPP matrix melts  
17 in the vicinity of 145°C. The melting of the blend consist of these two PPs (ca. in 50-50 wt%)  
18 is around at 155°C and its melting is reflected by one melting peak. The iPP component has  
19 advantageous effect on the crystallization of rPP. iPP and rPP are miscible polymer pair in  
20 molten state and the crystallization of the components take place simultaneously.  
21 Consequently, only one crystallization peak can be observed during the crystallization of  
22 iPP/rPP blends and the higher the iPP content is, the higher is the peak temperature of  
23 crystallization.  
24

27  
28  
29  
30  
31  
32  
33  
34  
35

36 The melting and crystallization characteristic of  $\beta$ -rPP composite based material after  
37 reprocessing is demonstrated in Figure 3. The peak temperature of crystallization ( $T_{cp}$ ) of the  
38  $\alpha$ -reinforcement, the  $\beta$ -matrix and the composites is in the vicinity of 112, 104 and 114°C  
39 respectively. The  $T_{cp}$  of  $\beta$ -rPP matrix is significantly higher than that of the non-nucleated rPP  
40 matrix (see in Figure 2a), which unambiguously indicates the presence of the highly active  
41 nucleating agent. The presence of Ca-sub results in even higher  $T_{cp}$  of the  $\beta$ -rPP composite as  
42 well compared to the  $\alpha$ -PP reinforcement. The  $\beta$ -nucleated matrix and composites have  
43 complicated melting peaks. The double melting peak at lower temperatures refers to the  $\beta$ -  
44 form, however the melting peak duplication hints at structural instability [34]. A perfection  
45 process within the unstable  $\beta$ -phase results in a  $\beta\beta'$ -recrystallization. Similar characteristics  
46 are represented by the melting trace of  $\beta$ -rPP composite based specimen, although a peak is  
47 shifted toward higher temperatures, because of the presence of iPP in the composites. The  
48 doubled melting peaks at 142 and 148°C can be attributed to the  $\beta\beta'$ -recrystallization as well,  
49 but it has to pointed out that the intensities of the melting peaks of  $\beta$ -form are less pronounced  
50  
51  
52  
53  
54  
55  
56

60  
61  
62  
63  
64  
65

1 because of the decreased amount of the nucleating agent. The  $\beta$ -rPP matrix contains 0.15 wt%  
2 Ca-sub, while the content of  $\beta$ -nucleating agent in the  $\beta$ -rPP composite based material is only  
3 the half of that in the  $\beta$ -rPP matrix.  
4

### 5 **The effects of number of reprocessing**

6  
7  
8 Figure 4 shows the melting and cooling curves of  $\beta$ -PP matrix and  $\beta$ -PP composite based  
9 material after reprocessing once and five times. When comparing samples reprocessed once  
10 and 5 times one can see that there was no considerable difference due to the cyclic  
11 reprocessing for both matrix and composite based specimen.  
12

13  
14  
15 The  $\beta$ -nucleating agent is still efficient even after five reprocessing steps, because of its good  
16 thermal stability, although during injection moulding the related standard for PP was  
17 followed, parameters of which did not support the formation of the  $\beta$ -crystals. The  
18 crystallization temperatures are at around of 120 °C, which is characteristic for nucleated iPP.  
19 Pronounced  $\beta\alpha$ -recrystallization process is reflected on the melting traces (see in Figure 4b)  
20 indicating the presence of the  $\beta$ -form. The  $\beta\alpha$ -recrystallization can be eliminated if the  
21 samples are not cooled below 100 °C [33]. The melting traces recorded after limited recooling  
22 step are represented in Figure 5. One can see that the  $\beta$ -nucleated matrix materials crystallized  
23 fully in  $\beta$ -form, but the composites also contain significant amount of  $\alpha$ -form due to  
24 considerably lower  $\beta$ -nucleating agent content. The reprocessability of the  $\beta$ -nucleating agent  
25 is shown only on  $\beta$ -PP composite based samples due to the higher  $\beta$ -content of the matrix.  
26  
27 The same tendency can be observed in the case of  $\beta$ -rPP materials. The melting curves do not  
28 indicate any degradation after multiplied processing in good agreement with MVR data.

35  
36  
37  
38  
39

### 40 **Mechanical properties**

#### 41 **Static tensile tests**

42  
43  
44  
45 The tensile strength (a) and modulus (b) values of iPP and rPP based systems are shown in  
46 Figures 6 and 7, respectively. When comparing the results of once and five times processed  
47 materials, the mechanical properties of the specimens do not modify considerably, which  
48 indicates that no pronounced degradation take place during multiplied reprocessing.  
49 Comparing the non-nucleated and  $\beta$ -nucleated matrix materials (both homo- and copolymer),  
50 it can be stated that the  $\beta$ -nucleation resulted in a slight decrement in tensile strength and in  
51 the Young's modulus, because of the presence of  $\beta$ -form. It should be noted that the  $\beta$ -  
52 nucleated matrix material have the lowest stiffness and tensile strength and the properties of  
53 the composite based ones is closer to that of the non-nucleated matrix material in the case of  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 iPP based materials. The relatively large stiffness and tensile strength of the  $\alpha$ -PP composite  
2 based specimens can be explained by the large  $\alpha$ -PP content of the samples (See in Figure 5).  
3 This is also true when comparing  $\alpha$ - and  $\beta$ -rPP SRPPC based materials. The modulus and  
4 tensile strength of rPP composite based specimen (iPP/rPP blends) were significantly higher  
5 than those of related matrix material, because of the presence of iPP phase.  
6

7  
8 From the result it can be stated further that there was no considerable change in the tensile  
9 properties if comparing the material processed once and five times.  
10

### 11 **Charpy impact tests**

12  
13 Figure 8 shows the Charpy impact strength results for iPP (a) and rPP (b) based systems.  
14 Based on the results it can be seen that the  $\beta$ -modification has improved the Charpy impact  
15 strength in case of matrix materials. The increasing of impact resistance is more pronounced  
16 in the case of homopolymer [20], because the rPP contains elastomers (PE), which improves  
17 the impact resistance as well. In the case of  $\beta$ -PP composites efficiency of the lower amount  
18 of  $\beta$ -nucleating agent may be more sensitive for the processing parameters, so the impact  
19 resistance did not increase significantly. In the case of rPP composite based samples the lower  
20 toughness is resulted by the approximately 50 wt% of  $\alpha$ -iPP content (see Figure 8a). It can  
21 also be concluded from the test results, that with increasing number of reprocessing, the  
22 Charpy impact strength did not decrease considerably.

### 34 **Conclusion**

35  
36 The goal of this paper was to study reprocessability and the melting behavior of the self-  
37 reinforced PP composite composed of fabric, woven from highly stretched split PP yarns as  
38 reinforcement and  $\alpha$  and  $\beta$  crystal forms of isotactic PP homopolymer and random PP  
39 copolymer as matrix materials. From the granulated materials different specimens were  
40 produced by injection molding and they were tested (MVR, DSC, tensile, Charpy).  
41  
42  
43  
44  
45

46 Based on the results the following conclusions can be drawn:

- 47 - self-reinforced PP composites can well be reprocessed without any loss of properties  
48 related to the properties of the matrix materials, thereby it is an excellent candidate for  
49 upcycling,  
50  
51
- 52 - the cyclic reprocessing (once and five times) did not result in considerable  
53 deterioration of the mechanical properties,

- based on the DSC results it can be stated that the used  $\beta$ -nucleating agent (Ca-sub) is still efficient after even five reprocessing cycles. However, it is necessary to apply suitable settings of injection molding.
- the random PP copolymer based SRPPCs (reinforced with PP homopolymer) became a one-phase blend after reprocessing. Their melting temperature and mechanical properties are between those of random copolymer and homopolymer.

## Acknowledgements

Answers to reviewers' comments

The authors want to thank the reviewers' comments which were very useful to improve the quality of the manuscript.

Answers to Reviewers' comments:

English wording needs considerable smoothing

**English wording has been improved.**

all abbreviations should be disclosed two-times, in the abstract and in the main text, respectively

**According to the reviewer's suggestion, it has been corrected.**

it was a pity that authors did not make any polaroptical investigations!

**Since the POM would not provide any additional information concerning the topic of our manuscript, the authors do not want to include micrographs into the paper in order not to exceed the 15 page limitation of the Journal.**

the DSC traces are treated only "qualitatively" - so their amount may be reduced

**In this work, 16 different materials were investigated. The authors demonstrated the changes qualitatively by DSC traces as the reviewer had pointed out. However, we think that the introduced curves are essentially important to represent the concept of the manuscript. Therefore, no changes were made at this point in order to keep the flawless introduction of the most important results.**

Abstract: last sentence is unclear - what was advantageous?

**Probable this sentence was written ambiguously. It has been corrected as follows: "The presence of  $\alpha$ -iPP reinforcement in the rPP based composites after reprocessing results in increased inclination for crystallization and consequently leads to improved mechanical stiffness compared to rPP neat matrices."**

Introduction: last sentence in penultimate paragraph - chain scission of the the matrix polymer (should be extended. Refs. 23-24 (p.4 top) are not in line with the corresponding citations.

**According to the reviewer's suggestion, the references have been corrected.**

section 1.1. paragraph above table 1: "7 processing temperatures": so the scrap fractions themselves had different thermal history?

**The polymer composites were manufactured at 7 different processing temperatures (to achieve different consolidation quality). Regardless of the consolidation quality the composite materials (separated according to only the matrix materials) were reprocessed and investigated together.**

section 1.3: Table 2 may be deleted and the related info inserted in the text

**Table 2 contains too many data, so to insert them in the text, their perspicuity would lose.**

section 1.6. last sentence on page 8: the last two sentences are fully obscure

**It has been corrected as follows: "iPP and rPP are miscible polymer pair in molten state and the crystallization of the components take place simultaneously. Consequently, only one crystallization peak can be observed during the crystallization of iPP/rPP blends and the higher the iPP content is, the higher is the peak temperature of crystallization."**

Editorial remarks

Our Journal prefers the term of "mass" instead of "weight", so please substitute weight by mass throughout the manuscript. (Example: sample mass, mass/% or mass loss etc.)

**According to the editor's suggestion, it has been corrected**
